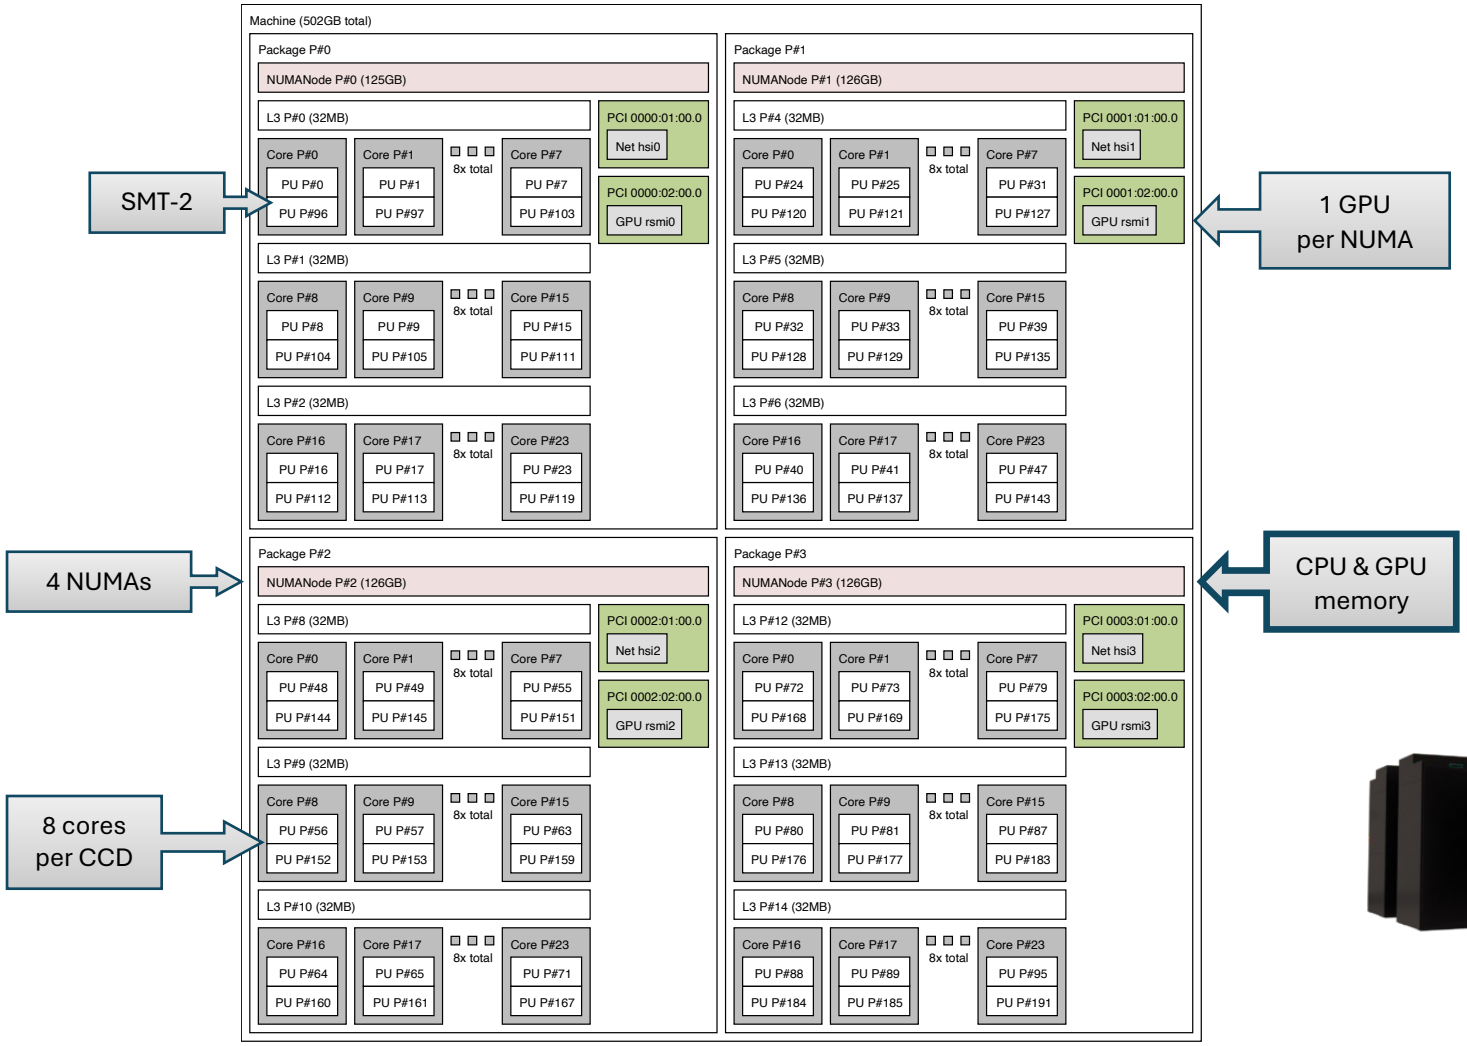
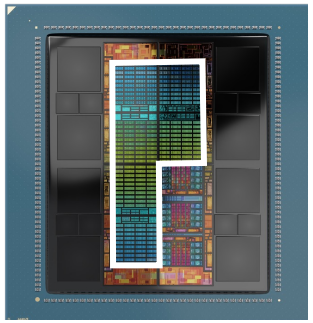
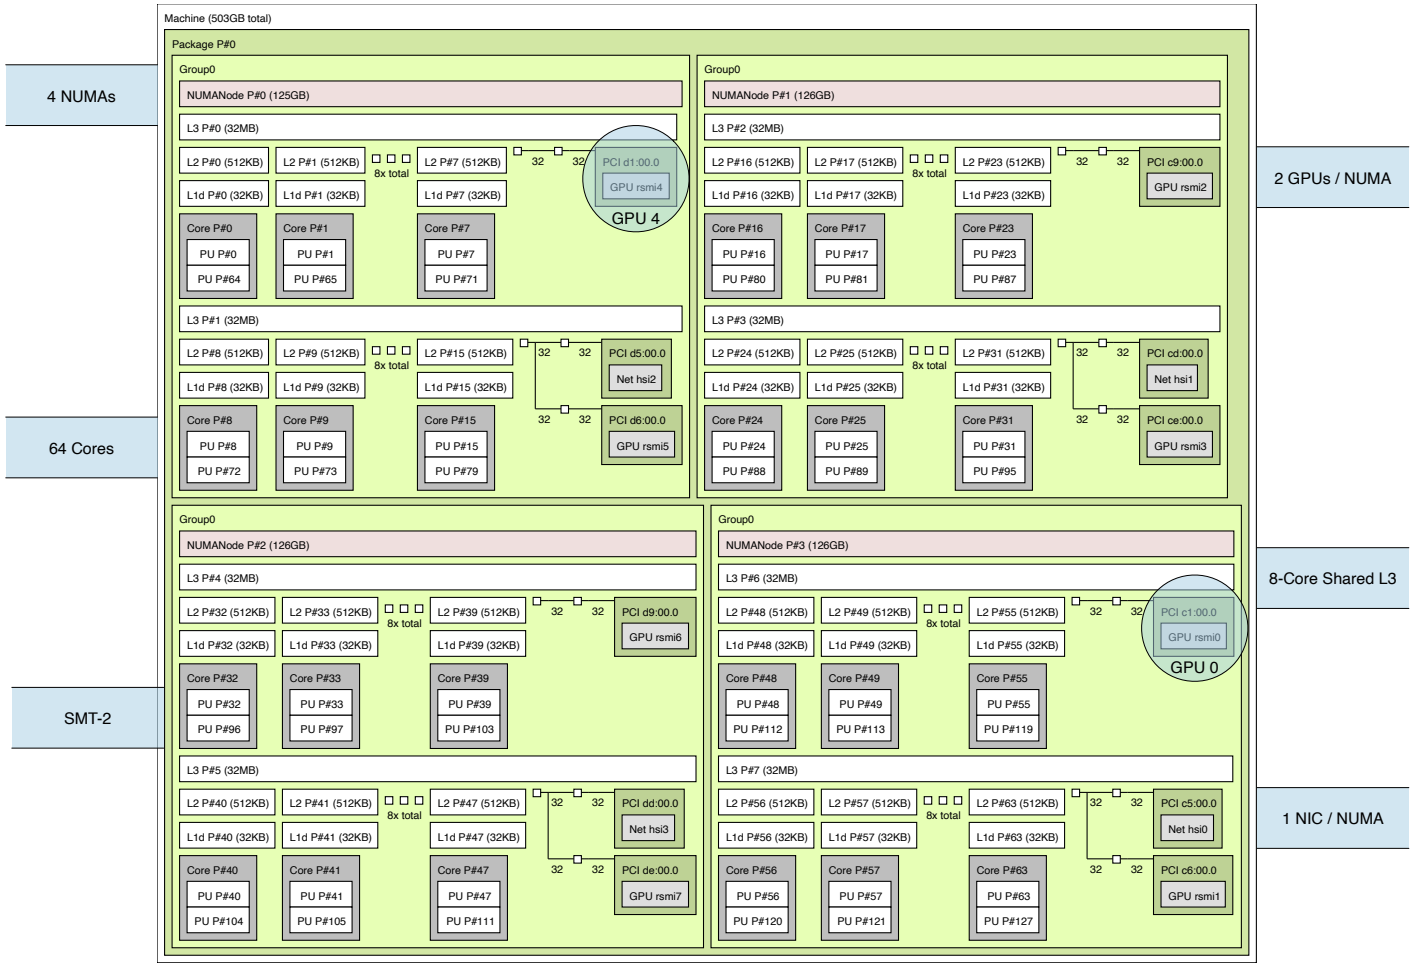
El Capitan's building block is AMD's MI300A APU





AMD Instinct MI300A APU

Mapping applications to the machine is hard



- What could go wrong?
  - Multiple threads running on a single core
  - Multiple GPU kernels sharing a GPU
  - Tasks launching kernels on non-local GPUs
  - Threads accessing remote memory
  - Etc.

mpibind is a memory-first, user-friendly algorithm

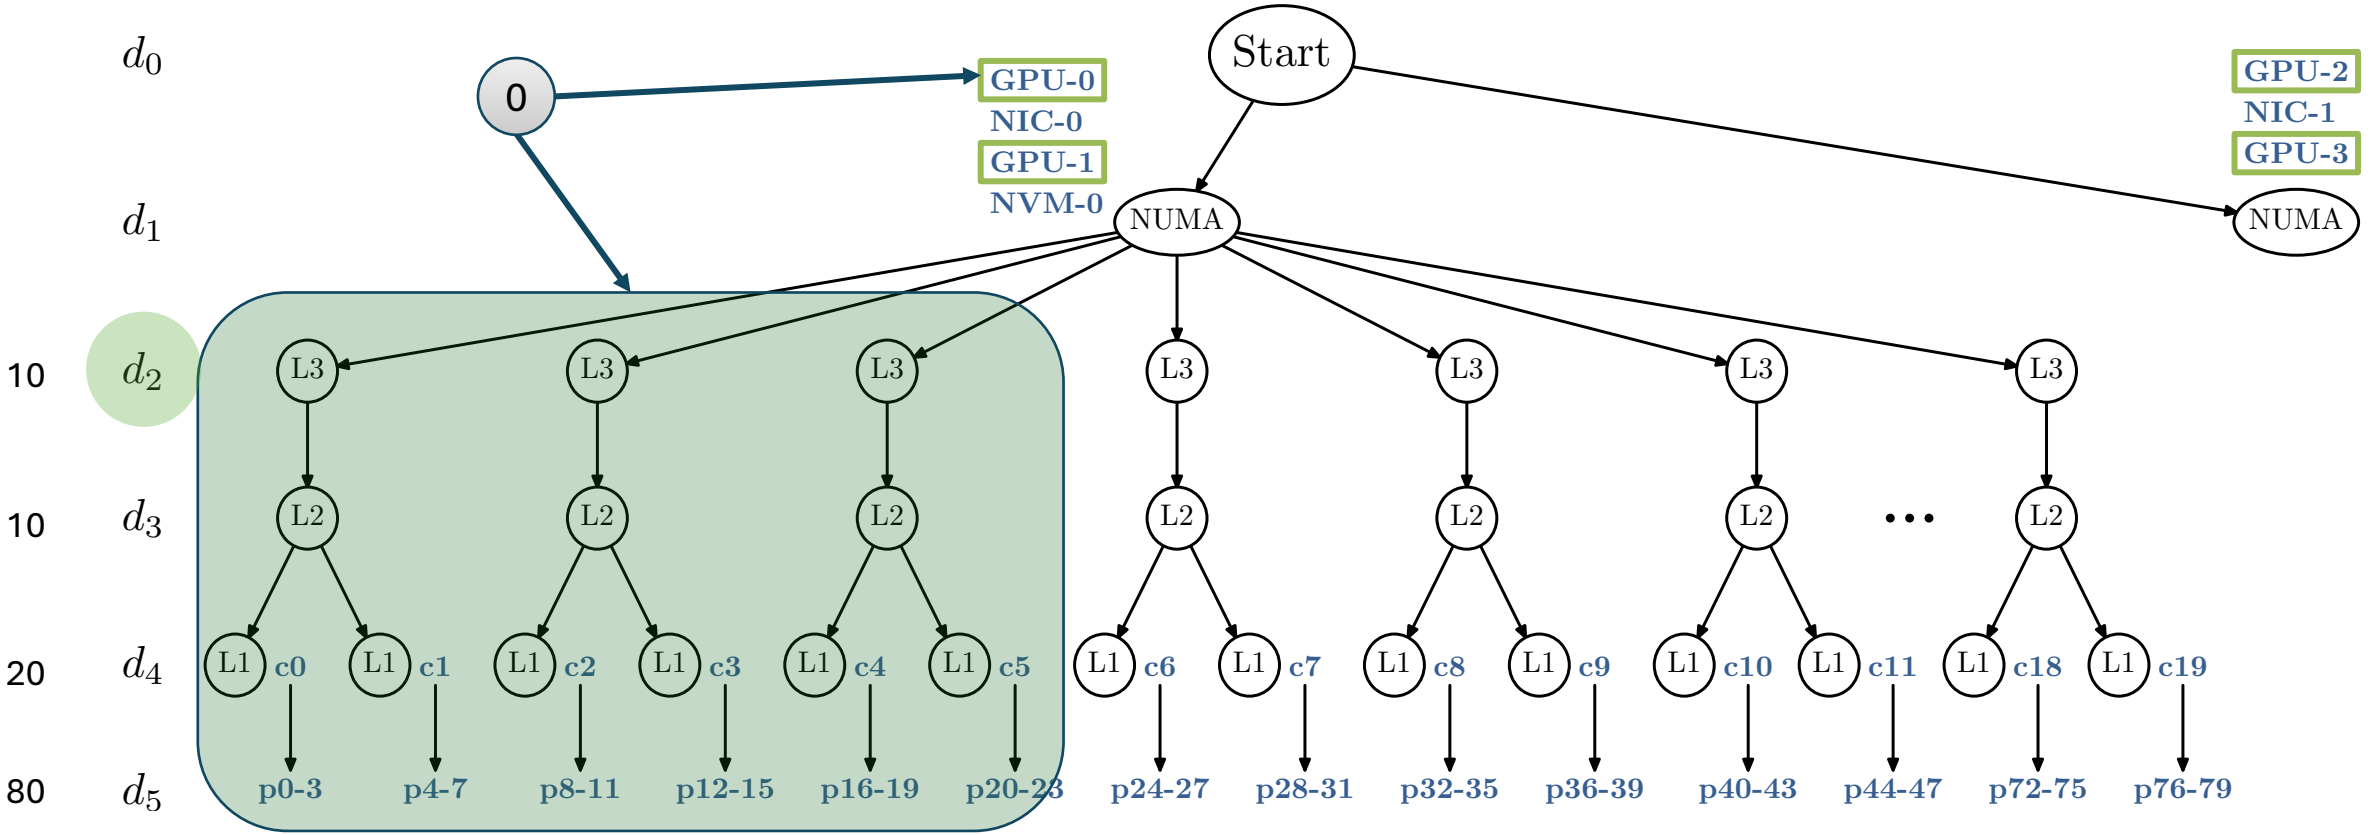
- Design principles
  - Driven by the memory system
  - Based on locality
  - Portable across architectures

mpibind

- Guiding principles
  - Provide a simple interface
  - Require minimal user input
  - Minimize remote memory accesses
  - Maximize cache per worker
  - Leverage compute/memory locality
  - Leverage architecture's features

mpibind uses the node topology to maximize memory and ensure locality

Tasks = 8
→Tasks/NUMA = 4 → Workers = 4
→ Vertices(d_2) = 10



Provides a simple interface & Requires minimal user input

JSM

```
# 8 MPI tasks across all cores and all GPUs on a CORAL node
jsrun -a 2 -c 10 -g 1 -r 4 -d packed -b packed:5 <prog>
```

mpibind

```
# 8 MPI tasks across all cores and all GPUs on a CORAL node
srun -n8 <prog>
srun -n8 -mpibind=on <prog>
```

Required	Number of tasks
Optional	Number of threads
User options	Greedy (true or false)
	GPU optimized (true or false)
	SMT (1 to num. HW threads per core)

mpibind

Provides portability across systems

- Counterexample

Intel MPI	I_MPI_PIN_DOMAIN	core, sock, numa, node, cache
	I_MPI_PIN_ORDER	range, scatter, compact, spread, bunch
MVAPICH2	MV2_CPU_BINDING_LEVEL	core, socket, numanode
	MV2_CPU_BINDING_POLICY	bunch, scatter, hybrid
	MV2_HYBRID_BINDING_POLICY	bunch, scatter, linear, compact, spread
OpenMPI	--bind-to, --rank-by	slot, hwthread, core, cache, socket, numa, board
	--map-by	+ node, sequential, distance, ppr:n:unit:pe=n
IBM Spectrum MPI	-aff	bandwidth, latency, cycle:unit

Provides portability across systems

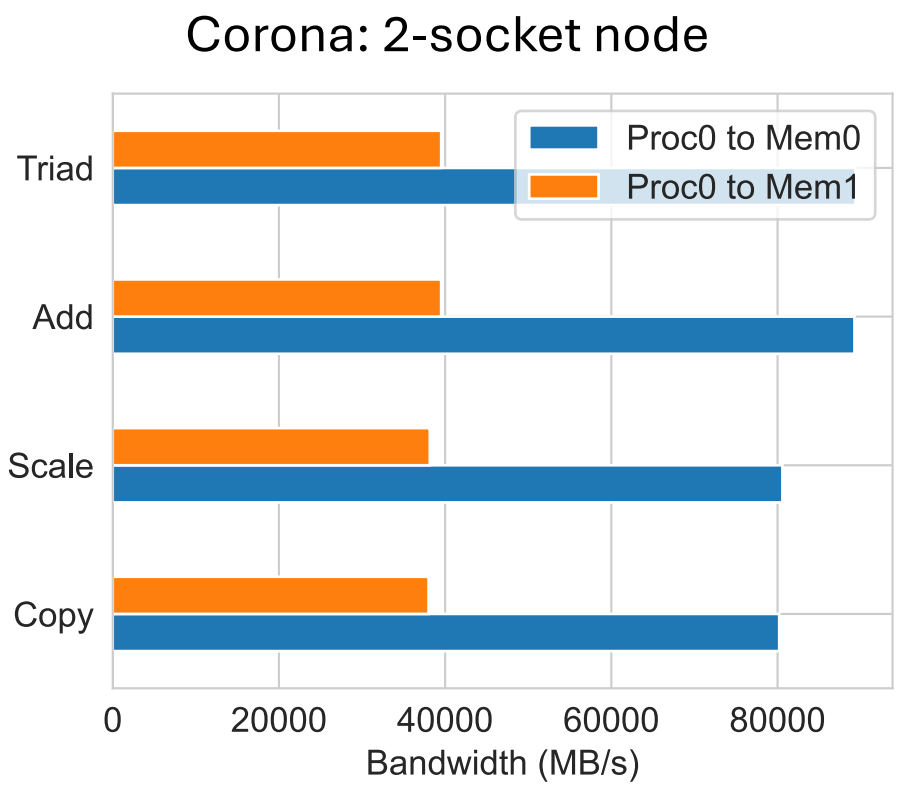
- Relies on abstract memory-compute tree
  - Portable Hardware Locality (hwloc)
- Affinity algorithm is separate from applying affinity
  - C interface
    `{Task} → {CPUs, GPUs, Thread mapping}`
  - Slurm plugin
    - Use job info as input to mpibind
    - Get mpibind mapping
    - Bind tasks
    - Set environment variables

mpibind

slurm
workload manager

Minimizes remote memory accesses

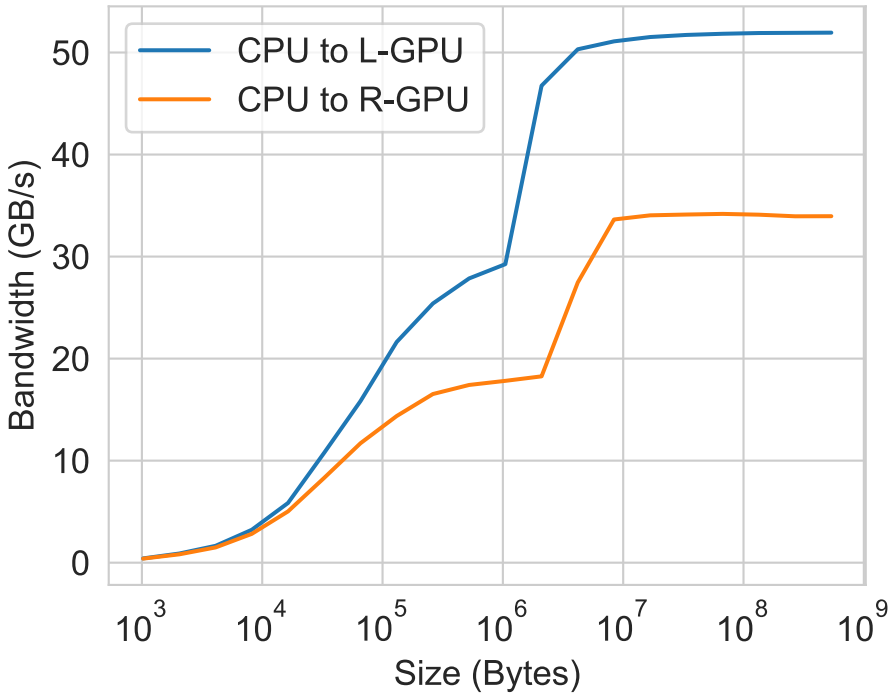
- Each task restricted to CPUs within a NUMA domain
- Leverage local memory
  - Spillover if necessary



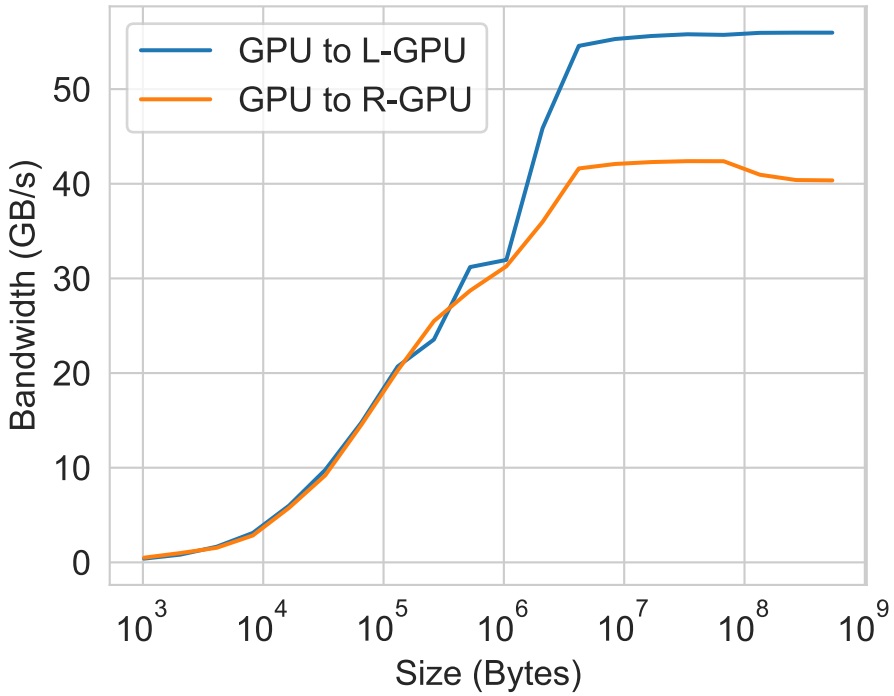
Selects local CPU-GPU sets

- Does it matter?

Up to 35% penalty for remote transfers



Up to 28% penalty for remote transfers

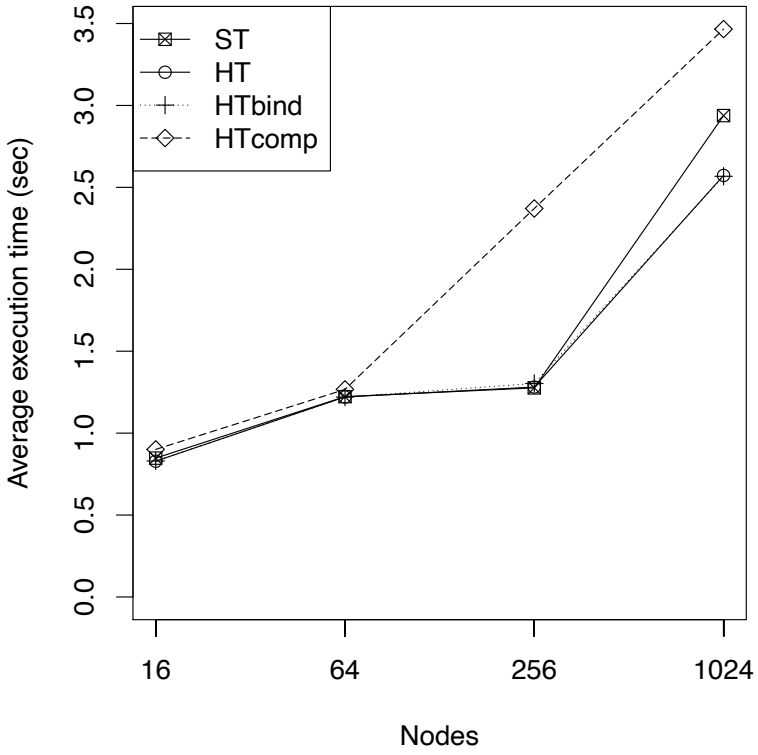


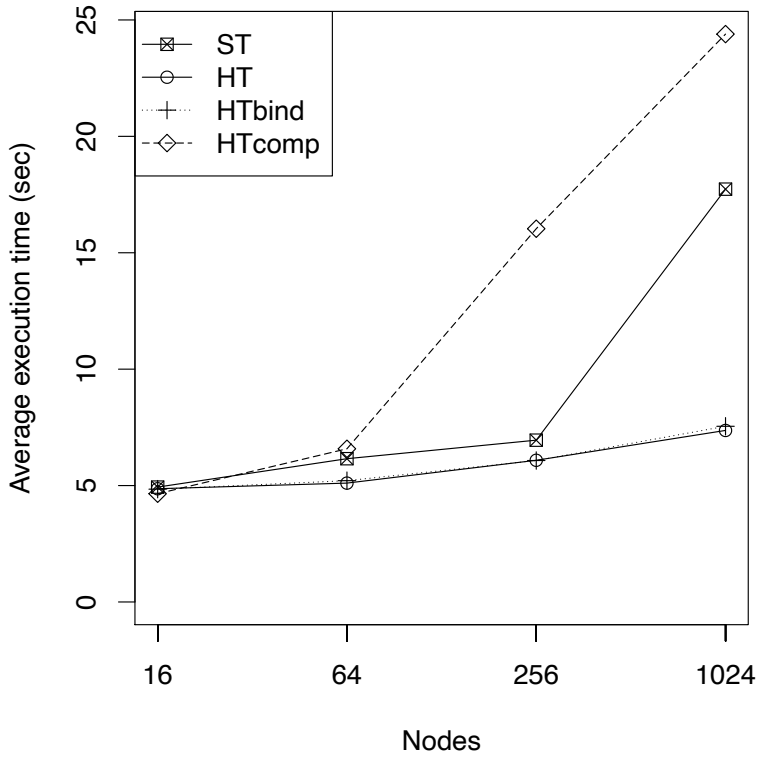
On LLNL systems with SMT we mitigate noise via thread specialization + mpibind

- Thread specialization
  - Application threads
  - System threads
- At boot time (TOSS)
  - Bind system processes to one HW thread of every core
  - *RHEL's tuna*
- At run time
  - Bind application to the other HW thread of every core
  - *LLNL's mpibind*
- But, applications have a choice!
  - `--mpibind=smt:<n>`
  - **Use all resources if needed**
- System noise studies
  - Must look at applications
  - Useful benchmarks
    - Parallel FWQ/FTQ
    - Synchronous collectives
  - Leon et al., IPDPS 2016, SC 2020

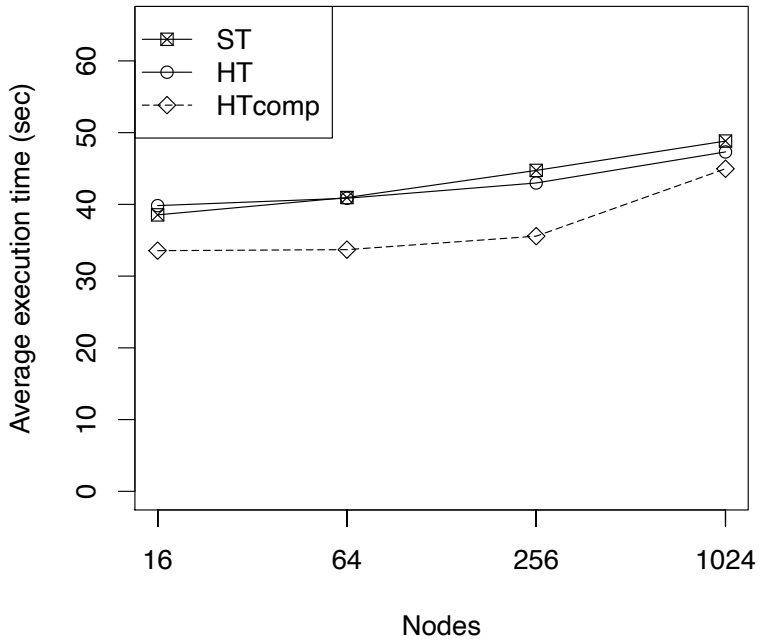
It matters how SMT is used by applications!

AMG and BLAST do not take advantage of additional HW threads, but significantly benefit from using them for system processes





pF3D can leverage the additional HW threads for compute



Leon et al., System Noise Revisited: Enabling Application Scalability and Reproducibility with SMT, IPDPS 2016

mpibind is available in Slurm as a SPANK plugin

- Open source
  - MIT license
  - Written in C
  - Depends on hwloc

- Building mpibind
  - GNU autotools

    bootstrap
    configure
    make
    make install

  - Spack

    spack install mpibind+rocm
    spack install mpibind+cuda

- Slurm SPANK plugin

  $ grep mpibind /etc/slurm/plugstack.conf
  required /usr/lib64/mpibind/mpibind_slurm.so default_off

https://github.com/LLNL/mpibind

mpibind is an excellent initial policy, but…

- Not suited for apps with dynamically changing mappings
  - Static policy set at job start
- Not intended for benchmarking
  - Performance of remote memory, remote GPUs, etc.
- Does not replace custom mappings
  - Resource manager's affinity masks, etc.

- Advanced use cases will be covered by Quo Vadis https://github.com/hpc/quo-vadis

Documentation is available

- Tutorials on mpibind and Slurm affinity
  https://github.com/LLNL/mpibind/tree/master/tutorials

mpibind helps applications with performance, portability, and productivity

- Performance
  - Leverages local memory and local devices
  - Mitigates system noise via SMT
  - Maximizes cache per worker
- Productivity
  - Provides a simple interface
  - Requires minimal user input
- Portability
  - Same algorithm across system architectures, MPI libraries, and resource managers
